

# Polar Coordinates

**Polar coordinates** are an alternative way of representing Cartesian coordinates or **Complex Numbers**.

A complex number  $z$

is completely determined by its real part  $x$  and imaginary part  $y$ . Here,  $j$  is the **imaginary unit**.

A polar coordinate  $(r, \varphi)$

is completely determined by modulus  $r$  and phase angle  $\varphi$ .

If we convert complex number  $z$  to its polar coordinate, we find:

$r$ : Distance from  $z$  to origin, i.e.,  $\sqrt{x^2 + y^2}$

$\varphi$ : Counter clockwise angle measured from the positive  $x$ -axis to the line segment that joins  $z$  to the origin.

Python's **cmath** module provides access to the mathematical functions for complex numbers.

## **cmath.phase**

This tool returns the phase of complex number  $z$  (also known as the argument of  $z$ ).

```
>>> phase(complex(-1.0, 0.0))
3.1415926535897931
```

## **abs**

This tool returns the modulus (absolute value) of complex number  $z$ .

```
>>> abs(complex(-1.0, 0.0))
1.0
```

## Task

You are given a complex  $z$ . Your task is to convert it to polar coordinates.

## Input Format

A single line containing the complex number  $z$ .

## Output Format

Output two lines:

The first line should contain the value of  $r$ .

The second line should contain the value of  $\varphi$ .

## Sample Input

```
1+2j
```

## Sample Output

```
2.23606797749979
1.1071487177940904
```

**Note: The output should be correct up to 3 decimal places.**
