Count Strings

A regular expression is used to describe a set of strings. For this problem the alphabet is limited to 'a' and 'b'.

We define R to be a valid regular expression if:
1) R is "a" or "b".
2) R is of the form "(R1R2)" where $R1$ and $R2$ are regular expressions.
3) R is of the form "(R1|R2)" where $R1$ and $R2$ are regular expressions.
4) R is of the form "(R1*)" where $R1$ is a regular expression.

Regular expressions can be nested and will always have have two elements in the parenthesis. ('*' is an element, '|' is not; basically, there will always be pairwise evaluation) Additionally, '*' will always be the second element; '(*a)' is invalid.

The set of strings recognized by R are as follows:
1) If R is "a", then the set of strings recognised = {a}.
2) If R is "b", then the set of strings recognised = {b}.
3) If R is of the form "(R1R2)" then the set of strings recognized = all strings which can be obtained by a concatenation of strings $s1$ and $s2$, where $s1$ is recognized by $R1$ and $s2$ by $R2$.
4) If R is of the form "(R1|R2)" then the set of strings recognized = union of the set of strings recognized by $R1$ and $R2$.
5) If R is of the form "(R1*)" then the the strings recognized are the empty string and the concatenation of an arbitrary number of copies of any string recognized by $R1$.

Task:
Given a regular expression and an integer, L, count how many strings of length L are recognized by it.

Input Format

The first line contains the number of test cases T. T test cases follow.
Each test case contains a regular expression, R, and an integer, L.

Constraints:
$1 \leq T \leq 50$
$1 \leq length(R) \leq 100$
$1 \leq L \leq 10^9$
You are guaranteed that R will conform to the definition provided above.

Output Format

Output T lines, one corresponding to each test case containing the required answer for the corresponding test case. As the answers can be very big, output them modulo 1000000007.

Sample Input

```
3
((ab)|(ba)) 2
((a|b)*) 5
((a*)(b(a*))) 100
```

Sample Output

```
2
```

```
32
100
```

Explanation

For the first case, the only strings recognized are "ab" and "ba". Of the 4 possible strings of length 2, 2 of them fit that expression.

For the second case, the regex recognizes any string of any length containing only a's and b's. The number of strings of length 5 recognized by this expression is $2^5 = 32$.

For the third case, the regex recognizes any string having one b, preceeded and followed by any number of a's. There are 100 strings of length 100 which have a single b in them.
